

ParallaxEffect Script Documentation

Overview

The **ParallaxEffect** script is designed to create a smooth parallax scrolling effect for 2D games in Unity. It automatically generates tile-based backgrounds, extending the image to the left, right, up, or down as required. This gives the illusion of depth and endless space by scrolling the background at varying speeds.

Requirements

- **GameObject:** This script must be attached to a GameObject that has a **SpriteRenderer** component.
- The background tiles are generated automatically at runtime, ensuring seamless transitions.

How to Use

1. **Attach the Script:** Add the `ParallaxEffect.cs` script to the GameObject with a SpriteRenderer component that you want to scroll.
2. **Configure the Properties:** You can modify the script's properties in the Unity Inspector to adjust the behavior of the parallax effect. Each field is explained below.

Inspector Properties

Update Mode

- **Type:** `UpdateMode`
- This property allows you to choose when the parallax effect should be updated. The available options are:
 - **Update:** The parallax effect is updated during the Unity Update cycle.
 - **LateUpdate:** The parallax effect is updated during the Unity LateUpdate cycle
 - **FixedUpdate:** The parallax effect is updated during the Unity FixedUpdate cycle

Parallax Speed

- **Type:** `Vector2`
- This defines the speed at which the background tiles will scroll. The `x` value controls horizontal movement, and the `y` value controls vertical movement.
 - **X Axis Speed:** Adjusts the speed of the background movement horizontally (e.g., left and right).
 - **Y Axis Speed:** Adjusts the speed of the background movement vertically (e.g., up and down).

Scroll X

- **Type:** `bool`
- If enabled, the background will scroll horizontally. Disable this if you only want the background to scroll vertically.

Scroll Y

- **Type:** `bool`
- If enabled, the background will scroll vertically. Disable this if you only want the background to scroll horizontally.

Setup Steps

1. **Prepare the Background:** Ensure the background sprite is correctly set on the `SpriteRenderer` component attached to the `GameObject`.
 2. **Assign the Script:** Drag and drop the `ParallaxEffect.cs` script onto the `GameObject` containing the background sprite.
 3. **Adjust Speed:** In the Inspector, you can modify the **Parallax Speed** values for both horizontal (`X`) and vertical (`Y`) scrolling to suit your needs.
 4. **Enable or Disable Scrolling:** You can choose whether to enable **Scroll X** or **Scroll Y** depending on whether you want horizontal or vertical scrolling, or both.
 5. **Set the Update Mode:** Adjust the **Update Mode** property to decide whether the parallax effect should be updated during the regular `Update` cycle or the `LateUpdate` cycle.
-

Example Usage

1. Open the included scenes to see examples of the `ParallaxEffect` script.
2. Enable or disable the different background `GameObjects` to see the different parallax images.

3. In play mode use WASD to control the player and see the parallax effect
 4. There are 3 different scenes which show different horizontal and vertical settings
 5. All background are included as a prefab to allow you to easily drop them into your game
-

Conclusion

The **ParallaxEffect** script is a powerful yet easy-to-use tool for creating parallax scrolling backgrounds in your Unity 2D games. By tweaking the properties, you can achieve various scrolling effects that add depth and immersion to your game world.
